(Received 8 January 2015; accepted 9 April 2015; published online 22 April 2015)

The spatial and temporal evolution of parametrically excited geodesic acoustic mode (GAM) initial pulse is investigated both analytically and numerically. Our results show that the nonlinearly excited GAM propagates at a group velocity which is, typically, much larger than that due to finite ion Larmor radius as predicted by the linear theory. The nonlinear dispersion relation of GAM driven by a finite amplitude drift wave pump is also derived, showing a nonlinear frequency increment of GAM. Further implications of these findings for interpreting experimental observations are also discussed. © 2015 AIP Publishing LLC.

I. INTRODUCTION

Geodesic Acoustic Modes (GAMs)1,2 are finite-frequency components of zonal structures (ZS)3,4 unique in toroidal plasmas, which could be spontaneously excited by microscopic drift wave (DW) type turbulence,5 including drift Alfvén waves (DAWs), and in turn, are capable of scattering DW/DAW into stable short radial-wavelength domain.6–9 Therefore, GAM may regulate the turbulence intensity and the associated wave-induced transports.10,11 The excitation of GAM by DWs can be described by parametric decay instability,12,13 where the DW pump \(\omega_0, k_0\) decays into a DW lower sideband \(\omega_1, k_1\) and a GAM \((\omega_G, k_G)\), and selection rules of frequency and wavenumber matching conditions are satisfied.

It is known that GAM has a finite linear group velocity due to finite ion Larmor radius (FILR) effects, and this linear group velocity is typically radially outward, consistent with GAM continuum due to radial temperature profiles. For GAM with \(k_r \rho_i \ll 1\), its linear group velocity is \(V_G = C_G \omega_G k_r^2\), with the linear dispersion relation given as \(\omega^2 - \omega_G^2(1 + C_G^2 k_r^2)\).2 Here, \(\omega_G = \sqrt{T_e/T_i + \frac{7}{4} v_t^2 R_0}\) is the local GAM frequency in the fluid limit, \(v_t \equiv \sqrt{2T_i/m_i}\) is the thermal ion velocity, \(R_0\) is the major radius of the torus, \(k_r\) is the radial wavenumber, \(\rho_i = m_i c v_i / (eB_0)\) is the ion Larmor radius, and \(C_G\) is an order unity coefficient. This linear group velocity of GAM has been discussed in several works2,14,15 and is shown to have important consequences on the nonlinear excitation of GAM by DWs and changes the absolute/convective nature of the parametric instability.8,16 Radial propagation of GAM has been observed in several experiments.17–19 and qualitative agreement between the experimental results and linear theory has been obtained.19,20 However, in-depth analysis of the experimentally obtained dispersion results lead to the conclusion that even though a quadratic dependence of GAM frequency on its radial wavenumber, qualitatively consistent with linear theory of KGAM,19 is indeed obtained, the coefficient for FILR effects is much larger than that predicted by linear theory.14,21 This discrepancy has also been found in numerical simulations,15 where the measured radial propagation velocity of the DW driven GAM is used to determine the coefficients of FILR effect, and is found to be much larger than unity. Up to now, there is no first-principle-theory-based explanation of this “enhanced FILR effect,” although a general theoretical framework exists to formulate it with all necessary physics ingredients.8 In fact, we will show in this work that this discrepancy could be due to nonlinear effects.

We note that GAM is an \(n = 0/m \simeq 0\) mode, with \(m = \pm 1\) sidebands and possibly higher order ones (depending on the perpendicular wavelength), such that it is generally not driven unstable by expansion free energy of the plasma. Here, \(m\) and \(n\) are, respectively, the poloidal and toroidal mode numbers in the Fourier mode structure representation adopting straight field line toroidal flux coordinates.22 Thus, GAM, in general, could be observed when it is nonlinearly driven by ambient turbulence, and in this case, the spatial-temporal evolution of GAM is significantly affected by the DW nonlinear drive. It has been pointed out in Ref. 8 that the nonlinearly driven GAM propagates at a much larger nonlinearly coupled group velocity in the presence of DW. As a result, the propagation of GAM and experimental observations should also be interpreted taking nonlinear effects into account. In this work, we shall further study the spatial-temporal evolution of the nonlinearly coupled DW-GAM system more in detail in order to analyze its implications to experimental observations. The rest of the paper is organized as follows: the theoretical model used in this work is presented in Sec. II, which is then solved in Sec. III for the spatiotemporal evolution of the coupled GAM-DW system. The possible applications of our theory to interpretation of experimental observations and numerical results are also presented. Finally, a brief summary is given in Sec. IV.

II. THEORETICAL MODEL

The equations describing the nonlinear interactions between GAM and DW are derived using gyrokinetic theory.2,8 Assuming that the DW is constituted by a constant-amplitude
pump wave and a lower sideband with a much smaller amplitude due to GAM modulation, the normalized coupled nonlinear equations describing GAM excitation by DW are then given as Eqs. (9) and (10) of Ref. 8

\[
\begin{align*}
(\partial_t + \gamma_s + i\omega_p - \omega_s - iC_d\omega_s\rho_i^2\partial_i^2)A_S &= \Gamma_0\delta', \\
(\partial_t(\partial_t + 2\gamma_G) + \omega_G^2 - C_G\omega_G^2\partial_i^2)\delta &= i\omega_G\Gamma_0\partial_i^2A_S.
\end{align*}
\]

Here, \(\delta \equiv \partial_t A_G/\pi\) is related to the GAM electric field with \(x \equiv i(z,\omega_pT_s/N)^{1/2}\) and \(x_t \equiv 1 + \delta P_+/(\epsilon n_0\delta\phi)\) an order unity coefficient,23 \(\delta P_+\) is the perturbed perpendicular pressure due to the DW pump scalar potential \(\delta\phi\) in the \(k_z\rho_i \ll 1\) limit. Meanwhile, \(A_G, A_P, \text{and } A_S\) are, respectively, the radial envelopes of GAM, DW pump, and lower sideband, and \(\Gamma_0 \equiv (x_cT_s/\omega_pT_c)^{1/2}c_{0,r}AP/B\) is the normalized pump wave amplitude. Furthermore, \(\gamma_s\) and \(\gamma_G\) are the Landau damping rates of DW sideband and GAM, \(\omega_p\) is the pump DW frequency, and \(\omega_s\) is the diamagnetic drift frequency. The kinetic term in Eq. (1), i.e., the term proportional to \(C_d\), comes from finite radial envelope variation due to the coupling between neighboring poloidal harmonics. The expression for \(C_d\) can be derived from Eq. (19) of Ref. 24, and one has \(C_d \sim O(\epsilon/(\omega_p^2\rho_i^2))\) with \(\epsilon\) being the safety factor, \(q \equiv dq/dr\) its radial derivative, and \(\epsilon = r/R_0\). On the other hand, the kinetic term in Eq. (2), i.e., the term proportional to \(C_G\), comes from FILR of GAM. Thus, \(C_G \sim O(1)\) and its detailed expression can be obtained from Eq. (9) of Ref. 21. Other notations are standard. We note that the governing Eqs. (1) and (2) are derived from quasi-neutrality condition assuming both GAM and DW are predominantly electrostatic perturbations. Electrons respond adiabatically to \(k_z \neq 0\) perturbations, i.e., DW and \(m \neq 0\) poloidal sidebands of GAM, while ion responses are solved assuming \(q \gg 1, k_z\rho_i \ll 1\), and \(|\omega_o| \sim |\omega_s|\) for DW. We note that even though turbulence usually refers to a broad spectrum of nonlinearly interacting DWs, in the present analysis, we have considered the nonlinear interactions of GAM with a single-\(n\) DW in order to elucidate the nonlinear effects on the radial propagation of GAM due to interaction with finite-amplitude DWs. Since for each DW with toroidal mode number \(n\), the interactions with the corresponding GAM are coherent, we may expect that in the presence of DW turbulence consisting of multiple-\(n\) modes, the net nonlinear effects would be an appropriate sum/integral of the nonlinear effects of individual-\(n\) modes considered here. System nonuniformities in Eqs. (1) and (2), which may affect qualitatively the convective/absolute nature of the parametric process as shown in Ref. 8, are also ignored here in order to focus on the radial propagation of the parametrically excited GAM pulse.

III. SPATIALTEMPORAL EVOLUTION OF THE COUPLED DW-GAM SYSTEM

Equations (1) and (2) can be solved using two-spatial two-temporal scales expansion of \(\delta\) and \(A_S\), i.e., \(A_S = A_S(\tau, \zeta) \exp(ik_0\tau - i\omega_0t)\) and \(\delta = \delta(\tau, \zeta) \exp(ik_\theta - i\omega_0t)\) such that \(\partial_\tau = -i\omega_0 + \partial_\tau\) and \(\partial_\zeta = ik_0 + \partial_\zeta\), with \(\tau\) and \(\zeta\) denoting the slow temporal and spatial variations. In order to delineate the physics of GAM propagation, we can assume that the system is well above the excitation threshold.2 Thus, we can ignore \(\gamma_s\) and \(\gamma_G\) in Eqs. (1) and (2), and the coupled nonlinear equations reduce to

\[
(\partial_t + V_S\partial_\tau)\hat{A}_S = \Gamma_0\delta',
\]

\[
(\partial_t + V_G\partial_\tau)\hat{\delta} = \frac{1}{2}\Gamma_0(k_0^2 - 2ik_\theta\partial_\zeta)\hat{A}_S.
\]

Here, \(V_S = 2C_d\omega_s\rho_i^2k_0\) and \(V_G = C_G\omega_G\rho_i^2k_0\) are, respectively, the linear group velocities of DW sideband and GAM. We note that \(V_G\) and \(V_S\) have the same sign for typical tokamak parameters,28 such that the excitation of GAM by DWs is a convective amplification process, ignoring system nonuniformities.26,28 Furthermore, in deriving Eqs. (3) and (4), the following frequency and wavenumber matching conditions for resonant decay are applied:

\[-\omega_0 + \omega_p - \omega_s + C_d\omega_s\rho_i^2 = 0,\]

\[-\omega_0^2 + \omega_G^2 + C_G\omega_G^2\rho_i^2 = 0,\]

from where \((\omega_0, k_0)\) can be solved for.

Moving into the wave frame by taking \(\zeta = \zeta - V_c\tau\), with \(V_c = (V_S + V_G)/2\), the coupled nonlinear equations, (3) and (4), can be combined to yield the following equation describing the nonlinear spatial-temporal evolution of the parametrically excited GAM:

\[
\left(\partial_\tau^2 - V_0^2\partial_\zeta^2\right)\hat{\delta} = \frac{1}{2}k_0^2\Gamma_0\hat{\delta} - ik_0\Gamma_0\partial_\tau\hat{\delta}.
\]

Here, \(V_0 = (V_S - V_G)/2\). Letting \(\hat{\delta} = \exp(i\beta\zeta)A(\zeta, \tau)\), with \(\beta = k_0\Gamma_0/(2V_0^2)\), Eq. (5) reduces to

\[
\left(\partial_\tau^2 - V_0^2\partial_\zeta^2\right)A = \frac{1}{2}k_0^2\Gamma_0 + \beta k_0\Gamma_0^2 - \beta^2V_0^2A \equiv \hat{\eta}^2A.
\]

Physically, \(\beta\) can be interpreted as nonlinear modification to the GAM wave vector, which also affects the GAM frequency as shown below. Equation (6) can be solved and yields the following unstable solution:

\[
A = \frac{\hat{A}}{\sqrt{\pi\Delta k_0}}\int_{-\infty}^{\infty} dk \exp \left(-\frac{k^2}{\Delta k^2}\right)\exp \left[ik_0\zeta + \sqrt{\hat{\eta}^2 - k_0^2V_0^2}\tau\right].
\]

(7)

This solution corresponds to the initial condition

\[A = \hat{A}_0 \exp \left(-\frac{\Delta k_0^2\hat{\eta}^2}{4}\right),\]

at \(\tau = 0\). We note that this is the typical wave packet initial structure for parametrically excited GAM, with a spectrum width \(\Delta k_0\). Assuming \(|V_\tau\partial_\tau| \ll |\partial_\tau|\), i.e., convective damping due to FILR effects is higher order corrections to the temporal growth,2,23 the general solution, Eq. (7), can then be reduced to the following time asymptotic solution:

\[A = \frac{\hat{A}_0}{\Delta k_0\hat{\eta}_e} \exp \left(-\frac{\hat{\eta}^2}{4\Delta k_0^2}\right),\]

(8)
Here, \( \lambda^2 = (1/\Delta k_0^2 + V_s^2)/(2\eta) \), and it corresponds to GAM initial pulse broadening in time. The time asymptotic solution of GAM electric field is then

\[
\delta = \frac{A_0}{\Delta k_0 \lambda} \exp \left( \eta \tau + i \beta (\zeta - V_e \tau) - \frac{1}{4 \lambda^2} (\zeta - V_e \tau)^2 \right). \tag{9}
\]

One then readily has from Eq. (9) that the nonlinearly excited GAM is characterized by a nonlinear radial wavevector

\[
k_{NL} = k_0 - i \partial \ln \delta = k_0 (1 + \Gamma_0^2/(2V_s^2)), \tag{10}\]

i.e., the wavevector increases with pump DW amplitude, and is larger than that predicted from frequency/wavenumber matching conditions.

The real frequency of the excited GAM can also be obtained from Eq. (9)

\[
\omega_{NL} = \omega_0 + i \partial \ln \delta = \omega_0 + \frac{k_0 \Gamma_0^2 V_e}{2V_s^2}. \tag{11}\]

\( \omega_0(k_0) \) can be solved from the matching conditions, which can then be substituted into Eq. (11), and yield

\[
\omega_{NL} = \omega_G + \frac{k_0 \Gamma_0^2 V_e}{2V_s^2} + \frac{1}{2} C_G \omega_G \Gamma_0^2 \rho_i^2 = \omega_G + \frac{k_0 \Gamma_0^2 V_e}{2V_s^2} + \frac{C_G \omega_G \Gamma_0^2 k_{NL}^2}{2(1 + \Gamma_0^2/(2V_s^2))^2}. \tag{12}\]

This is the nonlinear dispersion relation of the parametrically excited GAM. We note that both \( V_0 \) and \( V_e \) are proportional to \( k_0 \), and thus, the nonlinear frequency shift due to the modulation of DW, \( k_0 \Gamma_0^2 V_e/(2V_s^2) \), is independent of \( k_0 \). Thus, finite amplitude DW will increase the frequency of the nonlinearly driven GAM. The frequency increment can be expressed as \( (e\delta\phi/T)^2(L_n/\rho) \) from our theory, which indicates an order of unity frequency increment for typical tokamak parameters. This may explain the existence of the higher frequency branch of the “dual-GAM” observed in HT-7 tokamak,19 which oscillates at a frequency much higher than other branch with the usual GAM frequency (the frequencies of the two co-existing “dual-GAMs” are, respectively, 12 and 21 kHz in shot 113901 (Ref. 19)). Another finding of the HT-7 experiment is the coefficient of FILR effect is \( O(10^2) \) larger than that predicted by linear theory.28 On the other hand, Eq. (12) shows that the coefficient for kinetic dispersiveness is, in fact, decreased by a factor \((1 + \Gamma_0^2/(2V_s^2))^2\). The reason why experimental analysis found an “increased” coefficient is that, in the analysis of experimental data, one employed the linear dispersion relation of GAM and used the expression \((\omega_{obs} - \omega_{loc})/(\omega_{loc} k_{obs}^2 \rho_i^2)\) to determine the coefficient \( C_G \).28 Here, the subscript “obs” denotes experimental observation, and “loc” denotes local continuum frequency of GAM. As we have shown in Eq. (12), \( \omega_{obs} - \omega_{loc} \) contains the kinetic dispersiveness as well as the order one nonlinear frequency increment \( k_0 \Gamma_0^2 V_e/(2V_s^2) \); which, thus, can lead to an over-estimation of the coefficient \( C_G^NL \).28 The effective coefficient obtained in this way is \( C_G^NL \sim (e\delta\phi/T)^2(L_n/\rho) \sim O(10^2) \) for typical tokamak parameters, which is significantly larger than that predicted by linear theory. Our nonlinear theory, thus, provides a possible explanation of experimental observations. It can also be used to explain the \( O(10^2) \) increase of the FILR coefficient from numerical simulations.15

The coupled GAM and DW sideband wavepacket propagates at a nonlinear group velocity \( V_c = (V_s + V_G)/2 \), which is much larger than the linear group velocity of GAM due to \( |V_s| \gg |V_G| \), \((|\omega_p| \approx |\omega_s| \gg |\omega_G|) \) for resonant decay. Thus, to interpret the propagation of GAM nonlinearly excited by DW turbulences including DAW, linear theory of KGAM22,23 is not adequate, and one must instead apply nonlinear theory. We note only that while both the real frequency and wavevector of the excited GAM depend on the amplitude of the pump DW, the nonlinear group velocity is determined by \( k_0 \) from matching conditions and is independent of the pump amplitude. Thus, for the comparison of experimental observations with analytical theory, the nonlinear group velocity may be a better candidate.

The coupled nonlinear GAM and DW sideband equations, Eqs. (1) and (2), are solved numerically. Here, we fix \( C_L = C_G = 1 \), \( \omega_G = 0.1 \), \( \omega_P = \omega_s = 1 \) and study the coupled nonlinear equations by varying \( \Gamma_0 \). The dependence of the nonlinear wavenumber \( k_0 \) on pump amplitude is given in Fig. 1, where the dots are the wavenumbers from numerical solution, the diamonds are the wavenumbers obtained from Eq. (10), and the solid curve is obtained from matching condition. For the parameters we have here, the wavevector solved from matching conditions is \( k_0 = 0.32 \). We may see from Fig. 1 that our nonlinear theory fits well with the numerical results, and it reduces to \( k_0 \) as \( \Gamma_0 \) approaches 0.

The comparison of the numerically measured nonlinear group velocity with our theory is presented in Fig. 2, where the dots are numerical results and the diamonds are obtained from \( V_c = (V_s + V_G)/2 \), and \( V_s \) and \( V_G \) are defined with \( k_0 \). We note that for the parameters we used in numerical solution, \( V_s = 0.64, V_G = 0.032 \), and \( V_c = (V_s + V_G)/2 = 0.34 \gg V_G \). Very good agreement between numerical results and analytical theory (<3% discrepancy) is obtained here, suggesting that experimentally observed radial propagation of GAM must be understood using nonlinear theory.

![FIG. 1. Nonlinear wavenumber \( k_r \) vs. pump amplitude \( \Gamma_0 \).](https://example.com/fig1.png)
The nonlinear frequency of GAM is given in Fig. 3, where the dots are numerical results and the diamonds represent $\omega_{NL}$ from Eq. (11). Note that for the parameters we use here, $\omega_0 = 0.105$, and the nonlinear frequency from numerical solution increases with pump DW amplitude as predicted by our theory.

IV. CONCLUSIONS AND DISCUSSION

In conclusion, equations describing the spatial-temporal evolution of parametrically excited GAM initial pulse are studied both analytically and numerically. It is found that the parametrically excited GAM propagates at a nonlinear group velocity, which is the mean of the linear group velocities of GAM and DW, and is much larger than that predicted by linear theory of kinetic GAM. The wavevector of the excited GAM has a quadratic dependence on the amplitude of the amplitude; suggesting it as a good candidate for the comparison between experiments and analytical theory. Our nonlinear theory further shows that there is a nonlinear upshift in the wavelength, which is the mean of the linear group velocities of GAM and DW, and is much larger than that predicted by linear theory of kinetic GAM. The wavevector of the excited GAM has a quadratic dependence on the amplitude of the DWs, we have, in the present analysis, considered the modification of the GAM dispersion relation due to a single-$n$ DW with finite amplitude. This can be justified, since DW interactions with ZS, e.g., GAMs, have two components: a coherent part due to the interaction with the self-generated ZS and a random contribution due to interaction with ZS produced by other incoherent components of the fluctuation spectrum. In both cases, the coupling coefficient is proportional to DW intensity and, therefore, we focus here on the coherent GAM-DW interaction. Effects of system nonuniformities, which are shown to play important roles on the nonlinear interactions between GAM and DWs, are also ignored here. This will limit the applications of our nonlinear theory. To properly interpret global numerical simulations and/or experimental results, more in-depth investigations taking into account system nonuniformities will be needed.
